Unfortunately, without imposing very strict conditions on the functions to be minimized, it is not possible to guarantee that an n-dimensional minimization algorithm produces results which are correct to within some prescribed tolerance, or that the effect of rounding errors has been taken into account. We have to be satisfied with algorithms ...

Derivative-free optimization is a discipline in mathematical optimization that does not use derivative information in the classical sense to find optimal solutions: Sometimes information about the derivative of the objective function  $f$  is unavailable, unreliable or impractical to obtain. For example,  $f$  might be non-smooth, or time-consuming to evaluate, or in some way noisy, so that methods ...

In numerical analysis, Brent's method is a root-finding algorithm combining the bisection method, the secant method and inverse quadratic interpolation. It has the reliability of bisection but it can be as quick as some of the less-reliable methods.

Py-BOBYQA is a flexible package for solving bound-constrained general objective minimization, without requiring derivatives of the objective. At its core, it is a Python implementation of the BOBYQA algorithm by Powell, but Py-BOBYQA has extra features improving its performance on some problems (see the papers below for details).

In this paper, we present a new model-based trust-region derivative-free optimization algorithm which can handle nonlinear equality constraints by applying a sequential quadratic programming (SQP) approach. The SQP methodology is one of the best known and most efficient frameworks to solve equality-constrained optimization problems in gradient-based optimization [see e.g. Lalee et al. (SIAM J ...
